#### ACKNOWLEDGMENTS

The authors wish to thank S. Wilcox, who aided in some of the WAZP II electronics construction, and J. Cantey, K. Fischer, and H. Dannelongue, who helped acquire the data at sea. C. Paulson and R. Baumann provided the Seabird salinities and temperatures as well as some shipboard meteorological observations.

## THE MILDEX EXPERIMENT

MILDEX, a mixed layer dynamics experiment, began October 21, 1983 and lasted until November 16, 1983. R.P. Flip, R.V. Wecoma and R.V. Acania rendezvoused at 34° N, 127° W to participate in joint observations of the mixed layer and upper ocean. This report contains data from the WAve Zone Profiler, WAZP II, deployed from the R.V. Wecoma.

The WAZP II is a vertically rising microstructure profiler with sensors designed to obtain kinetic energy dissipation rates and microstructure information near the sea surface. WAZP II was deployed over block periods during the cruise beginning October 25 and ending November 12, GMT. Work was done in daylight with the ship moving at about 1/2 knot (just enough to maintain heading into the swell). Time between casts was approximately nine minutes, with each drop lasting roughly two minutes.

## THE INSTRUMENT

The WAZP II microstructure probe is 1.7 m long and 5.7 cm in diameter. A nose cone contains 2 airfoil shear sensors (Undersea Technology Inc., Monterey, California), a fast thermistor (Thermometrics model FP07), a solid-state pressure sensor, and a conductivity sensor. Two WAZP II probes were used in MILDEX. Probe #6.83 was equipped with a Neil Brown conductivity sensor, and probe #7.83 had a Michael Head micro-conductivity sensor. The probe body is filled with mineral oil, and pressure is transmitted to the probe interior through a bladder. Inside the probe are batteries, pre-amplifiers, and associated circuitry. Signals are transmitted to a ship-board acquisition system through a data link consisting of 8 pairs of 32 gauge copper wire, a Kevlar core, and a polyurethane sheath. The data link also serves as a recovery line. Drag brushes are installed on the tail of WAZP II to maintain a steady vertical speed.

The WAZP II is operated in the rising mode by using toroidal foam buoyancy elements around the probe body. A ballast weight is attached to the recovery line, and the probe is allowed to descend to a chosen depth (usually less than 100 m). The ballast is then released, and the probe buoyantly ascends. The rise speed can be adjusted by changing the buoyancy. During MILDEX, a 55 cm/s rise

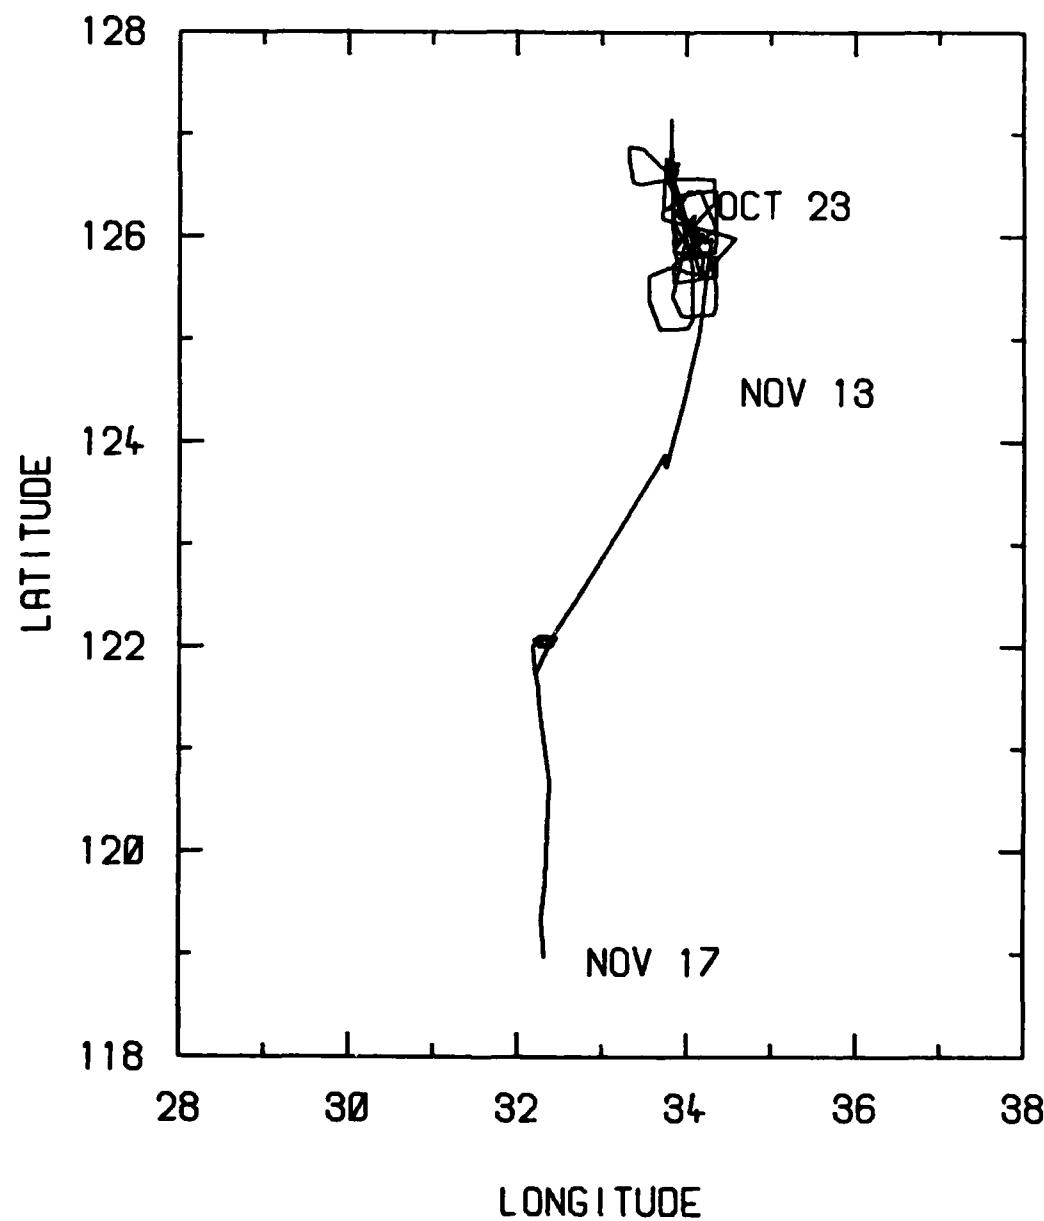

speed was used. The terminal velocity is reached a few meters above the release depth. Normally, the speed (as measured from the pressure) varies by  $\pm 5$  cm/s over most of the drop. Occasionally, the observed speed was as large as 65 cm/s in MILDEX. Within 1-2 meters of the surface, the speed usually fell to 40-50 cm/s, perhaps due to the wind-wave field, or possibly due to strong shears very near the surface.

On board ship, voltages were amplified, processed, digitized, and recorded on magnetic tape. Digitization was done with a 12-bit ADAC A/D converter controlled by an LSI 11/23 minicomputer. Voltages were digitized at 130 scans per second, each scan consisting of 16 words. In order to increase resolution near the surface, where gradients are small, temperature and conductivity were both independently amplified twice, using different gains and offsets. High gain temperature, low gain temperature, high gain conductivity, and low gain conductivity were filtered at 40 Hz with a 6-pole analog butterworth filter, and were recorded once each scan. Signals from the pressure pre-amplifier were filtered at 2 Hz, and were recorded once per scan. The two shear signals were amplified, differentiated, and filtered at 80 Hz with an elliptic filter. Each shear channel was recorded twice each scan, yielding an effective rate of 260 samples per second. Temperature and conductivity were also electronically differentiated before filtering. The temperature derivative was filtered at 45 Hz with an elliptic filter, and the conductivity derivative was filtered at 240 Hz with an elliptic filter. Temperature derivatives were digitized twice per scan, and the conductivity derivative was digitized 4 times per scan, giving an effective sampling rate of 520 samples per second.

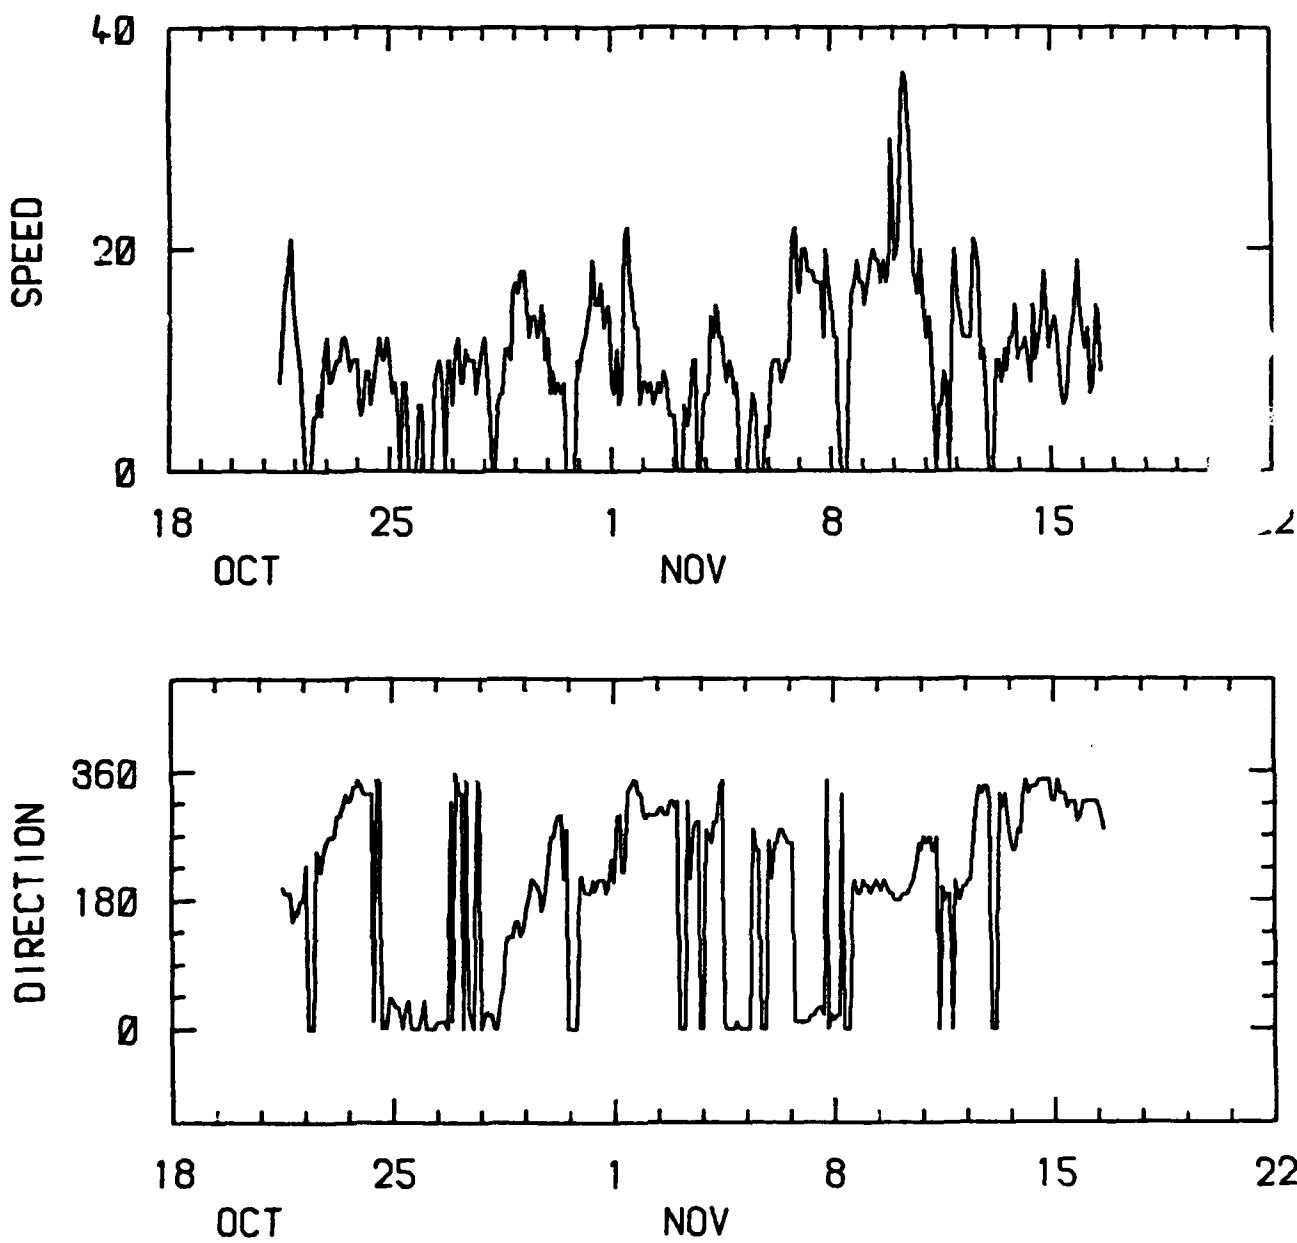

### THE DATA

This report contains two types of plots. The first type shows low gain temperature, temperature derivative, and shear, as a function of depth, illustrating near surface activity and pinpointing periods of turbulent activity. The data for these plots were averaged over approximately 2 cm. The second type of plot is a profile of temperature, salinity and  $\sigma_T$ , with corresponding units of  $^{\circ}\text{C}$ , parts per thousand, and  $\sigma_T$  units (data averaged over 20 cm). These plots are included for roughly every five drops per tape or at least one near the beginning and one near the end of each working period. Times and dates shown are GMT. Plots of meteorological data, ship position, and various sea surface parameters obtained from bridge observations are at the beginning of the report along with a detailed list of WAZP II drop information.

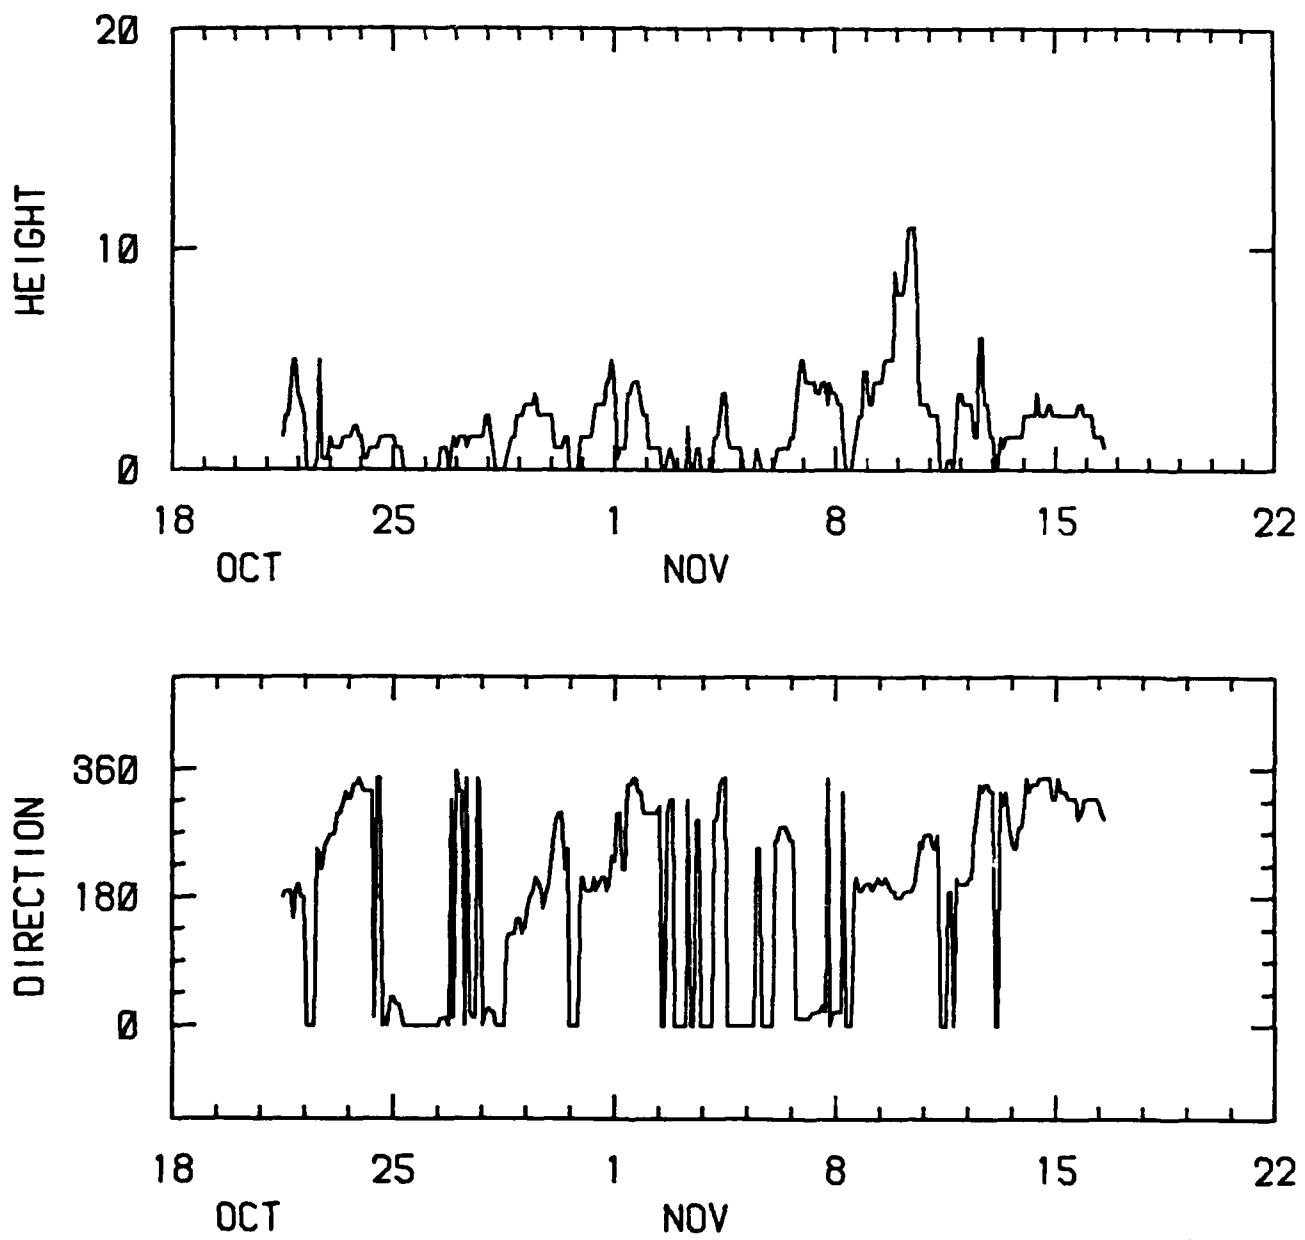

Conductivity comparisons from both units to a flow-through Seabird, and bottle salinity, indicated a marked shift in sensor calibrations, probably due to contamination of the conductivity sensors. Correction factors were applied to WAZP II conductivity in order to achieve agreement between WAZP II computed salinity and Seabird salinity. The WAZP II temperature measurements agreed well with Seabird temperatures, except the November 11 and 12 sampling periods, where an unknown discrepancy of 0.2  $^{\circ}\text{C}$  is apparent. This discrepancy has not yet been resolved, and it is not yet known which temperature is in error.
